I. INTRODUCTION

Road octane rating programs have been conducted periodically since 1963 by the Coordinating Research Council (CRC) Light-Duty Octane Technology and Test Procedures Group to investigate the relationships between the laboratory properties of a set of motor gasolines and the Road anti-knock performance of these fuels in selected groups of cars. The programs of 1971, 1973, 1975, and 1978 tested unleaded gasolines with a wide range of Research octane number (RON), Motor octane number (MON), and sensitivity. Variables evaluated were RON, MON, aromatics content, and olefins content. The testing was done by Octane Technology and Test Procedures Group participants from the oil industry at their own laboratories. The last program, conducted in 1980, evaluated heavy aromatics content and ethanol content in addition to RON and MON. This program revealed a large variation among cars and car models in their response to the test gasolines. Most of the thirty-seven test cars showed an adverse effect of adding heavy aromatics, and some of the cars showed beneficial effects for ethanol in the gasolines.

Because of the widespread interest in the use of alcohols and ethers as gasoline blending components, the present program was conducted to evaluate the effects of several oxygenates on gasoline octane performance and to evaluate the effects of car design features such as engine and transmission type.

II. SUMMARY

Five oxygenates were evaluated at two nominal concentrations, 5 and 10 volume percent, at both regular- and premium-grade octane levels: methanol (MeOH), ethanol (EtOH), isopropanol (IPA), tertiary butanol (TBA), and methyl tertiary butyl ether (MTBE). A blend of 5 percent MeOH and 5 percent TBA was also tested at both octane levels.

Two different techniques were used to analyze the data obtained in this program. The "conventional" method, used in all previous programs, analyzed data from all of the fuels together. Missing data were estimated using individual car regression equations. Data were analyzed by using multiple linear regression and analysis of variance techniques. Certain analyses were made with all-car average data; other analyses were made with data from individual cars. On an all-car basis, full-throttle Road octane numbers (Road ON's) were found to be well-predicted by the following equation containing only RON and MON:

$$\text{Road ON} = 29.96 + 0.289(\text{RON}) + 0.400(\text{MON})$$

The standard deviation and R^2 are 0.173 Road ON and 0.988, respectively, for this equation.

Multiple regressions were conducted to evaluate the effects of toluene, the oxygenates, and also squared RON and MON terms. It was concluded that $(RON)^2$ was needed to provide a good fit, and that toluene, TBA, and MTBE had beneficial effects on Road ON over and above their effects on RON and MON.

The second analysis technique used in this program took a different approach. Road ON prediction equations were developed for each car and for all cars using only the six hydrocarbon fuels. The all-car equation is:

$$\text{Road ON}_{\text{HC}} = 30.36 + 0.322(\text{RON}) + 0.347(\text{MON})$$

The standard deviation and R^2 are 0.261 Road ON and 0.989, respectively. A new term, called Road Octane Performance (ROP), was devised to represent the Road ON performance of the oxygenates as compared with hydrocarbon blending components. ROP is defined as follows:

$$\text{ROP} = (\text{measured Road ON}) - (\text{predicted Road ON}_{\text{HC}})$$

where the predicted Road ON is calculated using the prediction equations for the individual cars. A positive value indicates a Road ON benefit; a negative value indicates a deficit.

The addition of the oxygenates was found to cause nonlinear increases in all the ON's: Road ON, RON, and MON; the effects tended to level off with increasing concentration. For this reason, evaluation of the oxygenate effects was conducted separately for the low and the high concentrations.

Using ROP as the dependent variable, data analyses were conducted to evaluate the effects of the oxygenates. In the regular grade fuels at full throttle, all the oxygenates showed benefits, i.e., improved Road ON performance relative to hydrocarbon blending components. They gave higher Road ON's than expected judging by RON and MON. No trend was readily apparent in premium fuels.

Oxygenates in regular-grade fuels had highly significant beneficial effects in six-cylinder engines as a group (including both "inline" and "V" type engines), whereas the four-cylinder and V8 engines showed smaller, and non-significant, effects. With the premium fuels, none of the engine types showed significant effects; however, the V8's showed significantly poorer responses than the other engine types. There was no significant effect of transmission type.

The part-throttle results did not show any trends. This was probably due to the fact that only nine cars were tested at part-throttle, and that repeatability is poorer in part-throttle testing.

III. TEST PROGRAM

Testing was done by ten participating laboratories, as shown in Appendix A. The data were analyzed and the report written by the Panel shown in Appendix A. The text of the program proposal is presented in Appendix B.

Twenty-eight unleaded fuels, including four hydrocarbon fuels, two hydrocarbon fuels plus toluene, and twenty-two oxygenated fuels, were rated in duplicate in thirty-eight cars using the Modified Uniontown Technique (CRC Designation F-28-75 described in Appendix C), plus some additional instructions. All testing was done on chassis dynamometers. Ratings were obtained at full throttle* with all thirty-eight cars, and at the most critical part-throttle condition (occurring with manifold vacuum of 4 in. Hg (13.5 kPa) or greater above the full-throttle vacuum) with nine cars. Part-throttle ratings were determined from part-throttle primary reference fuel curves. The instructions also requested that the fuels be rated in random order, that three accelerations be made for each rating, and that the maximum speed be investigated for Modified Uniontown rating not exceed 60 mph (97 km/h).

IV. TEST FUELS

Five oxygenates - MeOH, EtOH, IPA, TBA and MTBE - were evaluated in each of two base gasolines, one just below the regular unleaded gasoline octane level [85-86 (R+M)/2] and one just below the premium unleaded gasoline octane level [89.5-90.5 (R+M)/2]. It was intended that the oxygenate blends would be at the regular and premium octane levels. The five oxygenates were blended into the base gasolines at nominal concentrations of 5 percent (low level) and 10 percent (high level) by volume. In addition, MeOH and TBA were tested in combination at a nominal concentration of 5 percent each. Each base gasoline was tested "neat" and with 15 volume percent toluene. Two special gasoline blends were included to improve the evaluation of the effects of RON and MON. The test fuel design is shown in Figure 1; the target test fuel specifications are shown in Table I.

* The ratings were actually obtained at maximum throttle, as described in the CRC E-15 Octane Number Requirement Technique. To make for easy reading, the words "full throttle" are used in this report.

RON, MON, R-100, and M-100 inspection data for the test fuels were supplied by many of the participants. R-100 and M-100 tests are RON's and MON's run on the front-ends of gasolines distilled to 100°C. The octane data were screened for outliers and then averaged. Five laboratories supplied analyses of oxygenate concentrations. These data are shown in Appendix D. There is no standard method of analysis for oxygenate concentration, and the specific technique used by each laboratory submitting oxygenate analyses was not stated. An available gas chromatographic method is described in the Journal of Chromatographic Science.⁽¹⁾ The data submitted were examined, outliers rejected, and the remaining values averaged. For all twenty-eight test fuels the measured properties critical to the test program are compared in Table II. Additional measured fuel properties are shown in Table III. Gas chromatographic analyses of the four hydrocarbon fuels are tabulated in Table IV. Fuel 4, regular-grade base gasoline plus 7.78 volume percent MeOH, showed phase separation at several laboratories. Hence, this fuel was not run in several of the test cars.

V. TEST CARS

Thirty-eight cars representing thirty different 1982 models were used in the program. Eight cars were equipped with manual shift transmissions, and thirty with automatic transmissions. The manual shift cars all had four-cylinder engines. There were twenty-three cars with four-cylinder engines; twelve with six-cylinder engines, of which nine were V-type and three were inline; and three with V8 engines. The test car models and their engine/transmission characteristics are shown in Table V. The odometer mileages ranged from 3,204 to 35,092 miles (5,156 to 56,475 km).

Though the program attempted to test a broad range of engine/transmission combinations, there is no assurance that the cars actually tested will represent the population of 1982 model cars on the road.

VI. BLENDING OCTANE NUMBERS

The RON, MON, R-100, M-100, and Road blending octane numbers (BON's) were determined for each oxygenate/concentration combination and toluene in the premium and regular base gasolines. Figures 2 and 3 show Road BON's plotted versus oxygenate concentration. In all but one case, the BON's were lower at the high concentrations. For this reason, the BON's were not averaged for each gasoline grade/oxygenate combination. Table VI shows BON's for the low and high oxygenate concentrations in both grades of gasolines, and for toluene at 15 volume percent.

Figures 4-6 were plotted to illustrate the effects of some of the variables on blending Road ON. The blending ON's shown on the figures are based on averages of the low and high concentrations. Figure 4 shows that the Road BON's were consistently higher for the oxygenates in the regular grade gasolines than in the premium grade gasolines. For toluene, the premium BON was higher, however. Figures 5 and 6 show that, in general, the Road BON was about halfway between the RON and MON BON's, as expected for hydrocarbon gasoline components. There were two exceptions, however: methanol/TBA had a low Road BON in the premium gasoline, and t-butanol had a high Road BON in the regular gasoline.

The front-end octanes, R-100 and M-100, generally showed much higher BON's than their counterparts, except in the case of toluene. This verifies the high octane quality and volatility of the oxygenates.

VII. ROAD OCTANE EQUATIONS

The individual Road ON's (Appendix I) were averaged over all thirty-eight cars to obtain mean values for use in developing Road octane equations. They are listed in Table VII for both full-throttle and part-throttle ratings. Missing data were estimated using the individual-car regression equations tabulated in Appendix E, Table E-I. Also included in Table VII are the standard deviations and the minimum and maximum Road ON's.

The average data were regressed using a standard multiple linear regression technique. The results of the regressions can be found in Appendix E, Table E-II for the full-throttle data, and Table E-III for the part-throttle data. Table VIII is a summary of the more pertinent full-throttle regression equations. The "goodness of fit" of the equation which uses only RON and MON is shown in Figure 7. As shown in Table VIII, the equation using $(R+M)/2$ was almost as good as the equation using RON and MON. The inclusion of a $(RON)^2$ term gave some improvement, as shown in Figure 8.

Inclusion of terms for the individual oxygenates along with RON and MON did not improve the correlation, and their coefficients were not statistically significant. Toluene, TBA, and MTBE together, however, did improve the prediction equation using RON, MON, and $(RON)^2$ terms (see Equation 39, Table E-II), as shown in Figure 9. The low standard deviation of 0.094 represents a substantial improvement over the equation with RON, MON, and $(RON)^2$. All six variables had highly significant effects. Toluene, TBA, and MTBE gave coefficients of 0.013, 0.032, and 0.031, respectively, which indicate 0.13, 0.32, and 0.31 Road ON boosts not accounted for by RON and MON (i.e., "bonuses") at 10 percent concentrations.

The inclusion of R-100, M-100 terms did not influence either the coefficients or the "goodness of fit."

Analysis made using all-car average Road ON's after sales-weighting each car did not change the correlation with RON and MON.

The best equation obtained for the part-throttle data is as follows:

$$\text{Part-Throttle Road ON} = 32.94 + 0.171(\text{RON}) + 0.449(\text{MON})$$

The standard deviation and R^2 for this equation are 0.336 Road ON and 0.938, respectively. Again, the coefficients calculated for the oxygenates were not significant (see Table E-III).

VIII. CALCULATION OF ROAD OCTANE PERFORMANCE (ROP)

The use of both laboratory octane numbers and oxygenate concentrations as independent variables in regressions on Road ON is undesirable because these variables are not independent. The concentration of oxygenate in each test fuel is highly correlated with the resulting RON and MON, relative to the base gasoline. To avoid this problem, a new dependent variable that included RON and MON was created to use in analyzing the oxygenate effects.

A Road ON equation was first developed for each test car for each gasoline grade using the three hydrocarbon fuels in each case. This was done for full-throttle data and part-throttle data (nine cars). The same was done using all six hydrocarbon fuels together (see Appendix F). It was found that the equations did not differ significantly between the two grades and, therefore, the six-fuel equations best represented the cars' Road octane performance with hydrocarbon fuels.

The new dependent variable, Road Octane Performance (ROP), was calculated by subtracting the predicted Road ON from the measured Road ON:

$$\text{ROP} = [\text{Measured Road ON}] - [\text{Predicted Road ON}]$$

$$\text{or}$$
$$\text{ROP} = [\text{Road ON}] - [a + b(\text{RON}) + c(\text{MON})]$$

This new variable represents the Road ON performance of the oxygenates as compared with hydrocarbon gasoline blending components. A positive value indicates a Road ON benefit, or "bonus"; a negative value indicates a deficit.

IX. AVERAGE RESULTS

Table IX presents the average Road ON and ROP for each test fuel for full-throttle and part-throttle test conditions. The latter averages represent only the nine cars that were tested at part-throttle. In the regular-grade fuels, the full-throttle ROP's for the oxygenate blends were generally positive, indicating improved performance relative to the base fuel which had an ROP of -0.25. No trend is readily apparent, however, in the premium fuels. The part-throttle data show roughly the same information, but the variations in ROP among the fuels appear to be much larger. Also, the Road ON's are much lower for part-throttle relative to full-throttle.

Table X presents the average Road ON and ROP for each test car for full-throttle, and for part-throttle where applicable. Among the full-throttle ROP's there are both positive and negative values, with an average of 0.02 Road ON -- essentially zero. The part-throttle average ROP was slightly negative at -0.09 Road ON. As with the averages for each fuel, the part-throttle Road ON's are generally lower than the full-throttle values, indicating that the part-throttle test is more severe.

X. ANALYSIS OF OXYGENATE EFFECTS

A. Nonlinearity of Oxygenate Effects

The effects of adding oxygenates to the base gasolines were evaluated using linear regression on every oxygenate/concentration level/grade/car combination. In each case, the dependent variable was ROP, and the independent variable was the oxygenate concentration. The results are shown in Appendix G for full-throttle data and in Appendix H for part-throttle data. Each effect is the regression coefficient for the oxygenate; it is a unit effect, i.e., the slope of the concentration curve at that concentration. The actual effect is determined by multiplying the unit effect by the portion of oxygenate added. If 10 percent were added, for example, the actual effect is one-tenth the unit effect.

TABLE IX

AVERAGE ROAD OCTANE NUMBERS AND
ROAD OCTANE PERFORMANCE (ROP) FOR EACH FUEL

| Fuel No. | Full Throttle* | | Part-Throttle** | |
|----------------------|----------------|-------|-----------------|-------|
| | Road ON | ROP | Road ON | ROP |
| Premium Grade | | | | |
| 14 | 91.56 | -0.05 | 87.44 | 0.02 |

* Except for the toluene blends, the values shown are averages of analyses submitted by five laboratories after rejecting outliers.

TABLE I
TARGET TEST FUEL SPECIFICATIONS

Octanes

Meet the octanes specified below for Fuels 1, 14, 27, and 28.

| | | |
|----------|---------------------|--------------------|
| Fuel 1: | (R+M)/2 = 85-86 | RON-MON = 6.5-7.5 |
| Fuel 14: | (R+M)/2 = 89.5-90.5 | RON-MON = 10-11 |
| Fuel 27: | (R+M)/2 = 85-86 | RON-MON = 9.5-10.5 |
| Fuel 28: | (R+M)/2 = 89.5-90.5 | RON-MON = 7-8 |

Oxygenates and Toluene

Meet the specified contents within +0.5% by volume. Methanol must be anhydrous. Ethanol must be at least 198-proof CDA-19 or CDA-20. Isopropyl alcohol, tertiary butyl alcohol, and methyl tertiary butyl ether must not contain more than 1% water.

Water Tolerance and Cleanliness

Final blends must be clean and bright, and they must not form water haze or droplets when chilled to 32°F. These inspections should be made on samples taken from 5-gallon cans prepared for shipping.

Volatility - All Fuels

| | |
|------------------------|-----------------|
| Reid Vapor Pressure | - 7-11 lb* |
| ASTM D 86 Distillation | |
| IBP | - 90°F Minimum |
| 10% Evaporated | - 110-150°F |
| 30% Evaporated | - 140-195°F |
| 50% Evaporated | - 180-250°F |
| 70% Evaporated | - 220-300°F |
| 90% Evaporated | - 285-370°F |
| EP | - 450°F Maximum |

* Fuels 27 & 28 - 8 lb maximum RVP.

Hydrocarbon Composition

Fuels 1 and 14 must be typical of unleaded regular and premium gasolines produced in the U.S. Fuels 1, 14, 27, and 28 must be blended with normal refinery components.

Other

| | | | |
|-------------------------|-----------|---------------------|------------------------------|
| Total Aromatics Content | | Lead Content | - 0.03 µg/gal max. |
| Fuel 1 | - 20-30% | Sulfur Content | - 0.05% maximum |
| Fuel 14 | - 30-40% | Manganese | - None to be added |
| Total Olefins Content | - 5-10% | Antioxidant | - 5 PTB (100% active) |
| Benzene Content | - 1% Max. | Blending Components | - Normal refinery components |

XI. FUTURE PROGRAMS

This program evaluated the effects on Road octane performance of adding six oxygenates to a premium and a regular base gasoline. In addition, it studied the influence of concentration level, transmission type, and engine type. The results are useful but they raise at least two questions:

- Why were the results quite different between the two grades?
- What are the shapes of the curves of response versus oxygenate concentration?

To answer the first question, a test program would have to include a number of base gasolines, as well as at least two oxygenates. The test fuels would have to be designed to independently evaluate octane level and hydrocarbon composition, i.e., the distribution of octane quality across the boiling range. To answer the second question, several oxygenate concentrations would be required. It is recommended that a test program be conducted in the near future to answer these questions.

F. Oxygenate Concentration Level Effects

Table XV shows average oxygenate effects and significance for each concentration level for each grade. Neither level was significant in the premium fuels, but both levels were highly significant in the regular fuels. In both grades, the low concentration level had the largest effect; however, the difference was not significant with the premium fuels. Figures 15 and 16 show the effects for both concentrations of each oxygenate. In all but one case, t-butanol in premium gasoline, the effect was larger at the low concentration.

G. Summary of Oxygenate Effects Results

Because of the non-linearity in the oxygenate response, the low-and high-concentration data were analyzed separately. The premium and regular grade fuels were analyzed separately because the results differed considerably between the two grades. The performance of the six oxygenates was about the same within each of the two grades. Only three of the premium grade oxygenate/concentration combinations were highly significant, but ten of the eleven regular-grade combinations were highly significant.

The oxygenate effects varied considerably among the engine types, but the average effects were significant for only the L6 and V6 engines in the regular grade fuels. The unit oxygenate effects were larger for the low concentration than the high concentration in the regular fuels. The overall average effects for the two concentrations were significant in only the regular fuels.

These results may be open to question because of the use of ROP rather than Road ON as the dependent variable. Because the ROP's are based on only six hydrocarbon fuels, the individual calculated oxygenate effects may be slightly high or low, or they all might be slightly biased upward or downward. Also, this method does not allow evaluating possible side effects of octane level on oxygenate performance within each gasoline grade. The ROP method, however, provided the only way to evaluate oxygenate performance independent of RON and MON, and the results are supported by other results in this report.

The Road ON equation study showed TBA and MTBE to have Road octane benefits independent of RON and MON. This is what the ROP analysis would have shown if the regular and premium-grade data were combined, as in the equation study. Also, the oxygenate blending octane number data showed relatively high values for Road ON, particularly in the regular grade. Another supporting finding is that the ROP results are not sensitive to variations in the Road ON equations used in calculating ROP. Using all twenty-eight fuels to develop the Road ON equations produced similar results, although the effects were generally a little smaller.

C. Oxygenate Effects

Full-throttle results are presented in Table XII. Oxygenate effects and significance are shown for the two grades, the six oxygenates, and the two concentration levels. Each effect is a unit effect, i.e., the theoretical effect of adding 100 percent of the oxygenate. In the premium grade fuels the statistically significant effects were methanol and t-butanol at the high concentration level. T-butanol had a beneficial effect of 4.97; methanol had an adverse effect of -3.69. Methanol/TBA had an adverse effect of -2.62, but the significance was slightly less than 90 percent.

In the regular grade fuels, all oxygenates except ethanol at the high concentration had highly significant effects. All effects were positive, indicating that the oxygenates were beneficial; they produced higher Road ON's than hydrocarbon blending components, at the same RON and MON.

Table XIII shows the part-throttle average oxygenate effects and significance for each oxygenate and each grade. The only significant effects were methanol/TBA in premium gasolines and IPA in regular gasolines, even though the effects were generally large. The small number of significant effects was probably due to the limited number of cars and to the poorer repeatability of the part-throttle test.

D. Gasoline Grade Effects

The oxygenate effects for the premium and regular gasolines are compared in Figure 12. The premium gasoline effects are considerably lower in every case than the regular gasoline effects. Three possible causes are the differences in the hydrocarbon composition of the two base gasolines, the differences in test fuel octane level, and the large differences in spark advance required.

E. Engine Type Effects

Table XIV shows average oxygenate effects and significance for each engine type for each grade. Although the premium-grade effects were not significant, there were two highly significant regular-grade effects; the L6 engines as a group showed the very large beneficial effect of 23.32, and the V6 engines showed an 11.77 effect. The only significant difference among the engine types, in the premium fuels, was that the V8 engines' effect was lower than those of the other engines. In the regular fuels, the L6 engines had larger effects, and the L4 engines had smaller effects than the other engines. The effects are presented graphically in Figures 13 and 14 for both low and high concentrations.

The full-throttle oxygenate effects are plotted versus concentration in Figures 10 and 11 for premium- and regular-grade gasolines, respectively. In all but one case the unit effect was less at the high concentration than at the low concentration. In fact, two of the oxygenates had effects that went from positive to negative as the concentration was increased, in the premium base gasoline. Because the response was different at the two concentration levels, the oxygenate effects were evaluated at both levels rather than averaging the two levels.

B. Analysis of Variance (ANOVA)

ANOVA's were used to determine what variables had significant effects. ANOVA's were conducted on the full-throttle oxygenate effects for premium and regular grades separately, and on the part-throttle data with the two grades combined. This was done because the full-throttle results were quite different in the two grades. Several car design parameters were evaluated to see if they affected ROP: transmission types (automatic or manual); engine types (cylinder configuration); engine model; and car model. Only engine type was retained for further analysis, because the others showed little or no influence on ROP. The fuel variables studied were oxygenate, oxygenate concentration, and gasoline grade. Table XI gives a summary of significance level for the main effects and interactions.

The low significance levels for the oxygenate variable in the full-throttle portion of Table XI indicate that there were no statistically significant differences among the oxygenates in either grade. There were large and significant differences, however, among the four engine types -- L4, L6, V6, and V8. The only other highly significant variable was oxygenate concentration level (i.e., the low level or the high level) in the regular grade fuels. This verifies the visually observed nonlinearity in these results. There appeared to be an interaction between engine type and concentration level in both grades, although the significance levels were less than 90 percent.

The part-throttle ANOVA showed the grade variable to be highly significant, meaning that the oxygenate effects differed between the two grades. The oxygenate variable was not highly significant, but the grade/concentration level interaction significance was nearly 90 percent.

Based on these ANOVA's, variables were selected for presentation and discussion in the following sections.

TABLE X

AVERAGE ROAD OCTANE NUMBERS AND
ROAD OCTANE PERFORMANCE (ROP) FOR EACH CAR

| Car No. | Full Throttle* | | Part-Throttle* | |
|---------|----------------|-------|----------------|-------|
| | Road ON | ROP | Road ON | ROP |

1982 FUEL RATING PROGRAM
ROAD OCTANE PERFORMANCE OF OXYGENATES

I. Introduction

Road octane rating programs have been conducted periodically by the CRC Motor Road Test Group to investigate the relationship between the laboratory properties of a set of motor gasolines and the road anti-knock performance of these fuels in a selected group of cars. The programs of 1971, 1973, 1975, and 1978 tested unleaded gasolines with a wide range of Research octane number (RON), Motor octane number (MON), and sensitivity. Variables evaluated were RON, MON, aromatics content, and olefins content. The testing was done by Road Test Group participants from the oil and automobile industries at their own laboratories. The last program, conducted in 1980, evaluated heavy aromatics content and ethanol content in addition to Research and Motor octane numbers. Because of the widespread interest in the use of alcohols and ethers as gasoline blending components, the proposed program for 1982 will evaluate several oxygenates.

The 1980 program revealed a large variation among cars and car models in their response to the test gasolines. Most of the 37 cars tested showed an adverse effect of adding heavy aromatics, and some of the cars showed beneficial effects for ethanol in the gasolines. It is believed that each engine type and transmission type is affected in a different way by the gasoline variables. The proposed 1982 program will investigate these car design features as well as the effects of oxygenates.

II. Objectives

In terms of the fuels, the main objective is to determine the effect on Road ON of each of five oxygenates--methanol, ethanol, isopropanol, tertiary butyl alcohol, and methyl tertiary butyl ether--independent of their effects on RON and MON. This will be done in two base gasolines, one at the regular unleaded gasoline octane level and the other at the premium unleaded gasoline octane level. Blending octane numbers will also be determined for the oxygenates.

The second objective is to evaluate the effects of engine and transmission type on the effects of the oxygenates. Up to one-half of the test cars will be used in a test design for this purpose.

III. Test Cars

The target is to test about 40 1982-model U.S. and imported cars. Subsets of the cars will be selected to evaluate the effects of engine and transmission types. For example, car Model X could be tested with four-cylinder engine and manual transmission, with four-cylinder engine and automatic transmission, with six-cylinder engine and manual transmission, and with six-cylinder engine and automatic transmission.

PREDICTION OF 38-CAR AVERAGE FULL-THROTTLE
ROAD ON BY RON, MON, (RON)², TOLUENE, TERTIARY
BUTANOL, METHYL T-BUTYL ETHER EQUATION
All Cars Tested

Other cars will be selected to provide a population of cars representative of the cars to be sold during the year 1982.

Engines of cars used for road rating the fuels in this program should not be altered from their factory configuration except as necessary for instrumentation required for the modified Uniontown technique. The cars should have at least 6000 miles and maximum octane requirements (CRC E-15 technique) of at least 86 RON with 1981 or 1982 FBRU fuels. Cars used for part-throttle ratings should have part-throttle octane requirements of at least 86 RON FBRU. In addition, spark timing should not exceed the following limits when rating any of the test fuels -- 10 degrees retarded to 25 degrees advanced relative to manufacturer's recommended basic timing.

IV. Test Fuels

The following oxygenates will be tested at both 5% and 10% by volume -- methanol, ethanol, isopropanol, tertiary butyl alcohol, and methyl tertiary butyl ether. In addition, methanol and tertiary butyl alcohol will be tested in combination at 5% each. As shown in Table I and Figure 1, the oxygenates will be tested in two different base gasolines; one representing regular unleaded gasolines with an $(R + M)/2$ of 85-86, and the other representing premium unleaded gasolines with an $(R + M)/2$ of 89.5-90.5. Each base gasoline will also be tested with and without 15% toluene. This will allow calculation of blending octane numbers for the oxygenates as well as toluene. Two special gasoline blends will be included to improve the evaluation of the effects of RON and MON. There will be six octane levels of the gasolines not containing oxygenates.

Test fuels specifications are shown in Table II. In addition to the usual specification for octanes, volatility, and miscellaneous items, the supplier will have to meet some special requirements. Maximum water contents are specified for the oxygenates, and the final blends will have to be clean and free of water. Each participant will check his samples for cleanliness and will run laboratory octane and volatility tests in addition to Road octane tests. R100 tests will be run to evaluate the front-end octane quality of the test fuels.

V. Test Procedure

All fuels are to be rated in duplicate in each car by the Modified Uniontown (CRC designation F-28-70) technique. Ratings are to be obtained at full throttle (maximum or wide open) and at the most critical part-throttle condition occurring with manifold vacuum of 4 in. Hg or greater above the full-throttle vacuum. However, part-throttle tests should not be conducted if ratings cannot be determined on all test fuels without exceeding the spark advance limits. Part-throttle ratings must be determined from part-throttle primary reference fuel curves. The fuels should be rated in a random order. At least three accelerations should be made for each rating. The maximum speed investigated for modified Uniontown rating should not exceed 60 mph.

It is recommended that portable electronic spark timing control systems be used in rating the fuels. These devices are more accurate and easier to use than other systems. More important, they are easy to install on each car; and, therefore, cars used in this type of program would be out of service for only a short time. This type of spark control can be obtained from:

Electronic Systems Design

317 W. University Drive
Arlington Heights, Illinois 60004
Telephone: (312) 398-0550

VI. Data Reporting

Data should be reported to CRC prior to December 1, 1982, using data forms to be provided. To aid in analysis, each participant is requested to report the manufacturer's recommended ignition timing. Also, the basic timing relative to top dead center must be reported for each modified Uniontown fuel rating. Other important details to be reported are transmission gear for full-throttle ratings, manifold vacuum for part-throttle ratings, and complete car information as indicated on the data forms.

In all cases, each participant is requested to report data for all items included on the data report forms. To assure legible copies, each participant is requested to use a soft pencil or black ink when completing the data forms in longhand.

VII. Data Analysis

Analyses will be conducted on both full-throttle and part-throttle data. Multiple linear regressions will be used to determine the effects RON, MON, the oxygenates, and toluene. Subsets of the cars will be used to determine the effects of transmission type and engine type. An overall analysis will be made using all cars after sales-weighting each car.

Analysis of variance (ANOVA) techniques will be used to evaluate individual contributions of cars, engines, transmissions, fuels, various interactions, and test error to the variability of the Road octane ratings.

⁴Base Gasoline B plus 15% toluene.

⁵Unleaded gasoline with (R + M)/2 = 85-86 ON and RON-MON = 9.5-10.5 ON.

⁶Unleaded gasoline with (R + M)/2 = 89.5-90.5 ON and RON-MON = 7-8 ON.

B-9
TABLE II

TEST FUEL SPECIFICATIONS

Octanes

Meet the octanes specified in Table I for Fuels 1, 14, 27, and 28.

Oxygenates and Toluene

Meet the specified contents within +0.5% by volume. Methanol must be anhydrous. Ethanol must be at least 198-proof CDA-19 or CDA-20. Isopropyl alcohol, tertiary butyl alcohol, and methyl tertiary butyl ether must not contain more than 1% water.

Water Tolerance and Cleanliness

Final blends must be clean and bright, and they must not form water haze or droplets when chilled to 32°F. These inspections should be made on samples taken from 5-gallon cans prepared for shipping.

Volatility - All Fuels

| | |
|------------------------|-----------------|
| Reid Vapor Pressure | - 7-11 Lb* |
| ASTM D 86 Distillation | |
| IBP | - 90°F Minimum |
| 10% Evaporated | - 110-150°F |
| 30% Evaporated | - 140-195°F |
| 50% Evaporated | - 180-250°F |
| 70% Evaporated | - 220-300°F |
| 90% Evaporated | - 285-370°F |
| EP | - 450°F Maximum |

* Fuels 27 & 28 - 8 Lb maximum RVP.

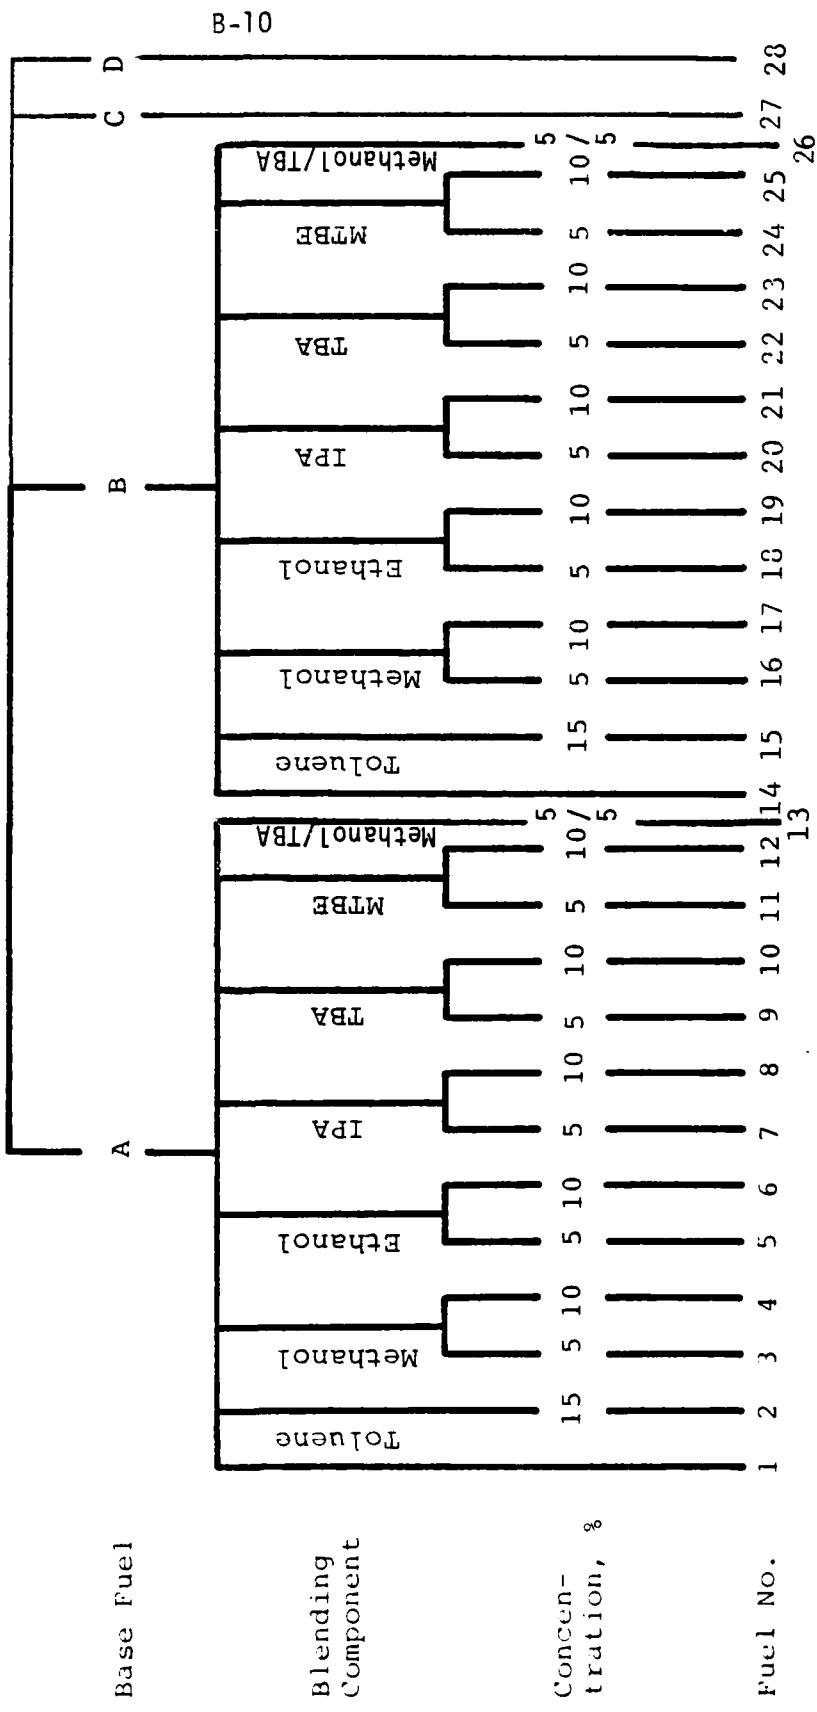

Hydrocarbon Composition

Fuels 1 and 14 must be typical of unleaded regular and premium gasolines produced in the U.S. Fuels 1, 14, 27, and 28 must be blended with normal refinery components.

Other

**MODIFIED UNIONTOWN TECHNIQUE
(CRC Designation F-28-75)**

This research technique has been developed for research purposes only and is not to be construed as a specification or standard, since the Coordinating Research Council, Inc. does not promulgate specifications or standards.

Prepared by the
Road Rating Techniques Study Panel
of the
CRC Light-Duty Octane Technology and Test Procedures Group

October 1975

Coordinating Research Council, Inc
219 Perimeter Center Parkway, Suite 400
Atlanta, Georgia 30346
(404) 396-3400

MODIFIED UNIONTOWN TECHNIQUE

(CRC Designation F-28-75)

A. SCOPE

The Modified Uniontown Test Technique is designed to determine a single road octane rating of a gasoline under level road accelerating conditions. The ratings are generally made at maximum throttle, but may be made at part throttle if desired or more critical. It is under these relatively severe conditions that the motoring public would probably encounter knock and thus be able to compare or evaluate fuel octane quality.

The Modified Uniontown Technique employs the vehicle's standard spark advance mechanism. The basic spark setting is varied until trace knock is obtained during acceleration for the primary reference fuel series and the gasoline(s) being rated. Trace knock is the lowest level of knock intensity that can be heard repeatedly.

The Modified Uniontown rating of a gasoline is the octane number of the RPF blend which would be expected to produce trace knock at the same basic spark advance as the test gasoline.

B. VEHICLE PREPARATION FOR TEST

The mechanical checks given below should be made as indicated. All adjustments should be made to conform with manufacturers' specifications unless otherwise specified in this section.

1. **Procurement Checks:** The checks listed below should be made upon initial receipt of vehicle for test. The vehicle should have accumulated sufficient mileage to provide adequate break-in and achieve deposit accumulation.

- (a) Compression pressures should be checked according to manufacturers' recommended procedures.
- (b) Check timing mark vs. TDC on cylinder number one piston, using a dial gage or equivalent.
- (c) Carburetors should be in good operating condition. If the vehicle is to be used for fuel rating for an extended period of time, it is recommended that carburetor mixture checks be made periodically to assure that the carburetor remains in the as-received condition.
- (d) Check the tappet clearance against manufacturers' specifications and adjust to limits.

B. VEHICLE PREPARATION FOR TEST - (Continued)

- (e) Install new set of spark plugs of recommended heat range (preferably after the deposit stabilization accelerations described in E2b). For continued high-speed operation, colder plugs may be desirable.
 - (f) Check distributor automatic spark advance mechanism for conformance to manufacturers' recommended specifications.
 - (g) Check fuel pump as per manufacturers' recommended procedures. Replace fuel filter element.
 - (h) Observe choke plate and make certain it is in wide-open position with the engine fully warmed up. Wire open automatic choke if necessary.
 - (i) Check throttle opening linkage for true wide-open throttle position, freedom from sticking, etc.
 - (j) Check heat valve to determine if it is free and operating normally. Allow it to function as in normal driving operation.
 - (k) Check crankcase breather or emission control system to insure satisfactory operation. Check air cleaner element and replace if necessary.
 - (l) Check the exhaust emission control system for proper operation.
 - (m) Check the fuel system evaporative control system, and also deactivate the fuel recirculating system, if so equipped, to obviate the possibility of flooding the fuel system.
 - (n) Check the operating temperature of the coolant thermostat to ascertain if it is operating correctly.
 - (o) Check the automatic transmission's shift characteristics for conformance with manufacturer's specifications.
 - (p) Check all belts for tightness and condition.
2. **Daily Checks:** The daily checks should include the items listed as (h), (i) and (j) in Paragraph 1 above, and also items listed below.
- (a) Check tire pressure.
 - (b) Check oil level.

B. VEHICLE PREPARATION FOR TEST - (Continued)

- (c) Check coolant level and note type and freezing point of coolant used.
 - (d) Operate the vehicle to test general performance characteristics, misfiring, surging, excessive noise, etc. A check of vehicle acceleration time under standard rating conditions at manufacturers' recommended spark timing would provide a good indication of overall vehicle performance.
 - (e) Check brakes for safe operating and reserve pedal.
 - (f) Make a visual check of the engine compartment just before start of test and periodically during testing to observe general mechanical condition of the engine. Look for water, oil and gasoline leaks, or any other sign of malfunctioning.
3. **Weekly or 1,000 Mile Checks:** Weekly or 1,000 mile checks should include items (a), (i), (j), and (k) in paragraph 1 above, and also items listed below.
- (a) Check auxiliary fuel systems for leaks, particularly if valving is used that might permit contamination of test or reference fuels.
 - (b) Check spark plugs for misfiring and gap to manufacturers' recommended procedures.

C. INSTRUMENTATION

1. **Spark Advance Measurement:** A method of accurately measuring basic spark timing should be provided. This can be done either mechanically or electronically. The equipment should be:
 - (a) Convenient to read from the passenger compartment during normal vehicle operation, unless remotely indicated or recorded.
 - (b) Capable of indicating spark timing within $\pm 1/2$ crank-angle degree.
 - (c) Unaffected by the vibrations, accelerations, or shock normal to full-throttle vehicle acceleration.

C. INSTRUMENTATION - (Continued)

2. **Spark Advance Control:** A mechanism should be provided to control spark advance from the passenger compartment. This control should be positive, with a minimum of hunting or backlash, and should not be affected by engine movement due to torque reaction.
3. **Engine Speed Measurement:** A method of measuring engine revolutions per minute should be provided which is:
 - (a) Capable of instantaneous reading and/or recording throughout the engine speed range.
 - (b) Convenient for reading from the passenger compartment during vehicle operation.
 - (c) Capable of indicating within an accuracy of \pm 50 rpm and with a repeatability of \pm 1% of the speed being read.
 - (d) Unaffected by the vibrations, accelerations, or shock normal to full-throttle vehicle accelerations.
4. **Manifold Vacuum Measurement:** A vacuum gage should be connected to the intake manifold and located where it can be seen by the driver. This is important for automatic transmission test cars in order that the car can be driven repeatedly at a low engine speed and at as low a manifold vacuum as possible without automatic downshifting to a lower gear.
5. **Temperature Measurement:** While temperature measurements are not directly necessary for fuel rating, they are important for checking the general operation of the engine and for controlling the operating conditions of the car when it is used on successive occasions. It is, therefore, suggested that thermocouples be installed in the following locations and the suitable instrumentation be provided to measure or record the following temperatures:
 - (a) Carburetor inlet air
 - (b) Engine coolant (block exit)
 - (c) Engine oil (sump or gallery)
 - (d) Automatic transmission oil
 - (e) Intake mixture (after stove area)

C. INSTRUMENTATION - (Continued)

6. **Weather Measurements:** It is suggested that the following ambient weather conditions be measured and recorded hourly during fuel rating tests:

- (a) Temperature
- (b) Humidity
- (c) Barometric Pressure

7. **Auxiliary Fuel System:** An auxiliary fuel system should be provided to facilitate convenient switching from one fuel to another. The auxiliary fuel line should be connected to the inlet side of the fuel pump, should be of minimum length, and should be routed in such a way as to avoid trapping fuel vapor. Installation should give consideration to safety as well as convenience of fuel handling. To minimize mixing of test fuels during fuel changeover, it is recommended that fuel settling bowls or large filters be blocked off and/or replaced by small filter assembly with the bowl mounted in an inverted position.

If an electric fuel pump is used, the fuel pressure at the carburetor should be checked to conform with the manufacturer's recommendation.

For cars used extensively for fuel ratings, carburetor bowl drain lines connected to a pump and waste can have been found to improve the speed and completeness of fuel system draining when changing from one fuel to another.

D. REFERENCE FUELS

Primary reference fuel blends should be prepared in two octane number increments over the range required to bracket the fuels being rated.

E. TEST PROCEDURE**1. Engine Warmup**

To stabilize engine temperatures, a minimum of fifteen miles of operation under road load conditions at speeds of 50 to 60 mph in top gear is required.

E. TEST PROCEDURE - (Continued)**2. Combustion Chamber Deposits Stabilization**

- (a) Cars should have a minimum of 2,000 deposit miles prior to use for road octane rating. The last 500 miles should be accumulated under medium to high speed conditions to insure stabilization of combustion chamber deposits.
- (b) Just prior to conducting each series of road octane rating tests, the following deposit stabilization run should be made:
 - (1) With the vehicle fully warmed up, set the spark timing to produce approximately light knock on tank fuel or other fuel which knocks near the manufacturer's recommended spark setting. (Knock should cover the expected range of testing.)
 - (2) At the above spark setting, make several accelerations over the speed range in which road ratings are desired. The accelerations should be conducted primarily at wide-open throttle employing part throttle only as required to limit maximum knock to light intensity.

3. Fuel Changeover**(a) Catalytic Device Cars**

Caution: Because of the installation of catalytic devices on these cars, permanent damage may result if the engine runs over lean or stalls. Therefore, changeover from one fuel to another must be accomplished without running the carburetor dry.

To eliminate contamination of the new fuel with residual amounts of the previous fuel, the car will be operated under the following conditions after charging with the new fuel: operate car for 2 miles at a maximum speed of 55 mph during which time four part-throttle accelerations at approximately 4" Hg manifold vacuum are made.

- (b) Non-catalytic device cars or catalytic device cars for which the manufacturer has provided written approval to run the carburetor dry with assurance the procedure will not damage the catalytic device.
 - (1) With one- and two-barrel carburetors, the carburetor shall be run dry at 55 mph, road load, in highest gear.

A P P E N D I X D

MEASURED OXYGENATE CONCENTRATIONS

F. REPORT AND INTERPRETATION OF DATA*

1. Calculate average basic spark advance for each fuel. Where rechecks have been run, use all valid spark advance observations.
2. Establish basic spark advance vs. octane number curve for reference fuels.
3. Obtain the octane number rating of each test gasoline by determining the octane number corresponding to the average basic spark advance value. The octane number is reported with the speed of maximum knock.
4. The reproducibility** of the Modified Uniontown Road Octane Number Test has been found to be about one octane number. Therefore, it is recommended that when the result of a single determination is to be reported it should be rounded off to the nearest 0.5 number. However, when multiple ratings are obtained, these individual ratings should not be rounded off, but the average may or may not be, depending on the individual laboratory's testing errors, and the ultimate utilization of the rating number.

* All calculations described herein may be accomplished either manually or by E.D.P. (electronic data process).

** Reproducibility is a quantitative expression of the random error associated with single determinations at different laboratories of a property of an identical material utilizing the same method. It represents the maximum difference between such measurements which would be expected to be exceeded in a given percentage of cases.

The reproducibility figures quoted above are calculated for one standard deviation which is normally exceeded in about 30% of the cases. Reproducibility is currently defined as the square root of the total testing variance minus the fuel variance.

(It must be noted that this reproducibility figure does not correspond to that of ASTM, which is normally exceeded in only one case out of 20.)

E. TEST PROCEDURE - (Continued)

- (c) Subsequent accelerations should be spaced at relatively constant time increments in order that repeatability of testing conditions is assured. Excessive braking between accelerations should not be utilized as temperature equilibria may not be reached before each successive acceleration is commenced. Experience with a particular vehicle and/or testing condition may dictate otherwise, but a time period of approximately 20 seconds between successive accelerations with several seconds at constant speed before the start of each acceleration is considered satisfactory to yield reproducible results.
- (d) The first one or more accelerations is exploratory, to enable the operator to become acquainted with the knocking characteristics of the fuel. At least two accelerations are made for recording of data. Basic spark advances required for trace knock intensity are recorded with the corresponding speed range of knocking.
- (e) With adequate instrumentation and adherence to procedural details, basic spark advances for trace knock accelerations generally will not differ more than one crankshaft degree. In such instances, two trace knock accelerations shall suffice and the average of the spark settings for the two accelerations shall be reported for the fuel.
If the spark advances for the first two trace knock accelerations will differ by more than one degree, one or more additional accelerations shall be made as required to establish a good average spark setting.
- (f) It is recommended that at least four different reference fuels be run to establish a reference fuel framework before running the test gasolines. Additional reference fuels should be interspersed with the test gasolines to complete the reference fuel framework in two octane number increments. Several reference fuels should be rechecked at intervals.

E. TEST PROCEDURE - (Continued)

- (c) Care should be taken not to operate at greater than light knock intensity because of the effect on combustion chamber temperatures and knock intensity during the remainder of the acceleration.
- (d) Excessively advanced or retarded ignition timings may lead to abnormal fuel ratings. Where possible, road rating determinations should be made within the range of 15 degrees advance to 10 degrees retard from the manufacturers' standard spark advance (recommended basic ignition timing plus centrifugal spark advance) at any speed.
- (e) The speed range investigated will normally extend to 3,000 rpm, but where conditions necessitate, should be extended beyond.

5. Details of Observations

- (a) The vehicles should be accelerated from as low a speed as practicable to as high a speed as desired. For manual transmission cars, the acceleration should be made in highest gear from the lowest speed giving reasonably smooth operation; the minimum engine speed will normally be about 700 rpm.

In the case of automatic transmission cars, the critical rating condition is dependent upon the transmission control system and may vary considerably among car makes. Operating characteristics of each vehicle should be explored to determine the drive ratio and throttle position which will allow operation at or near wide-open throttle over the widest range of engine speed with the gear selector in Drive position. It may be expedient to decrease intake manifold vacuum during the acceleration in accordance with a schedule predetermined for the particular test car.

- (b) Adjust basic spark timing to produce knock of trace intensity over as narrow a speed range as possible during the acceleration. Trace knock is defined as the lowest level of knock that is readily and constantly discernible to the ear. It is NOT the threshold between knock and no knock. Generally, the spark setting should not be changed during an acceleration except when encountering heavy knock. All comparative tests with different fuels must be made at the same trace knock intensity over the same speed range, recognizing that all fuels may not knock in the same portion of the speed range.

E. TEST PROCEDURE - (Continued)

- (2) With four-barrel carburetors, the primary float chamber shall be run dry at 55 mph, road load in highest gear. The secondary float chamber shall be run dry by going to wide-open throttle for short periods of time, being careful to avoid excessively high engine speeds. This must be accomplished in passing gear on those vehicles in which the secondary throttle plates are mechanically actuated by depressing the throttle beyond the detent position.

Caution: In cars equipped with automatic transmissions, care should be taken to maintain the car speed sufficiently high to keep the engine turning over. This is especially important to cars equipped with power brakes since a serious safety hazard may be encountered with a dead engine.

- (c) Charge the fuel system with a new test fuel and repeat the operations described in paragraphs (a) or (b).
- (d) After fuel changeover, make one preliminary acceleration before beginning Vehicle Rating Procedure and operate one-half mile at 50 to 60 mph, road load, to obtain stabilized conditions.

4. Operating Conditions

- (a) The vehicles should be tested at or as near maximum throttle as possible over the widest practicable speed range.

In the case of manual transmissions, this is wide-open throttle in top gear.

In the case of automatic transmissions, it is dependent upon the transmission control system and may vary considerably among car makes. Operating characteristics of each vehicle should be explored to determine the drive ratio which will allow operation at or near wide-open throttle over the widest range of engine speed.

- (b) Fuel ratings should be run on a smooth, level, straight road in either direction as long as audibility of knock is not affected by the wind. Tests shall not be conducted during periods of rain or rapidly changing weather conditions. Fuel ratings may also be run on a chassis dynamometer with proven good road correlation.
